**APPARATUS AND METHOD FOR PROVIDING ACCESS TO A DATA
STREAM BY A PLURALITY OF USERS AT A SAME TIME**

BACKGROUND OF THE INVENTION

5

1. Technical Field:

The present invention is directed to an apparatus and method for providing access to a data stream by a plurality of users at a same time. In particular, the present invention is directed to an apparatus and method for data stream splitter management for multiplexing access by a plurality of users to the same data stream.

2. Description of Related Art:

Presently, in distributed data processing systems, when a user is involved in a session making use of system resources, the session is typically set up so that a single user has access to the system resource during the session. Thus, only a single user is able to make use of the system resource until the session is completed and the system resource is released for use by another user.

Recently, systems have been devised for allowing multiple users to monitor the status of a system resource in a single session. Typically, in these systems, one user has full access to the system resources and is provided with the ability to use and/or modify these system resources. The other users involved in the session act as observers only and are not provided with full access to the system resources.

In either of the above systems, a problem arises if a first user wishes to share modifications to a system resource with a second user, and the second user wishes

Docket No. AUS9-2000-0257-US1

to share modifications with the first user. Each user must gain access to the system resource, make their modifications, release access to the system resource and then allow the other user to gain access and make their
5 modifications. The first user must then re-access the system resource to inspect the modifications of the second user. There is no mechanism by which both users can have full access to the system resource at approximately the same time.

10 Thus, it would be beneficial to have an apparatus and method whereby a plurality of users are provided full access to the same system resource in a same session at approximately a same time and be able to share the results of each user's access to the system resource with
15 other users in the session.

2000-0257-US1

SUMMARY OF THE INVENTION

5 The present invention provides an apparatus and method for providing full access to a data stream by a plurality of users at approximately a same time. The apparatus and method include a data stream splitter manager that listens for new connections from client devices. When a new connection from a client device is identified, the data stream splitter manager generates a pseudo-terminal for the client device and adds the client device and pseudo-terminal information to a data stream splitter table. In addition, if a data stream splitter is not already established for handling data transfer between the data stream splitter manager and a requested resource, a new data stream splitter may be generated to handle the data transfer.

Thereafter, the data stream splitter associated with the system resource searches the data stream splitter table for client devices that are sharing access to the system resource. The data stream splitter sends data from the data stream associated with the system resource to the pseudo-terminals associated with the client devices that are currently sharing the system resource in a sequential manner. Similarly, the data stream splitter receives input from the client devices via the pseudo-terminals and sends the input to the data stream associated with the system resource. In this way, each client device has an individual connection to the system resource but the output from the system resource is shared by each of the client devices. Additionally, each client device is provided with the output from the system resource in a realtime manner.

Other features and advantages of the present invention will be described in, or will become apparent, to those of ordinary skill in the art in view of the figures and the following detailed description of the preferred embodiments.

BRIEF DESCRIPTION OF THE DRAWINGS

The novel features believed characteristic of the invention are set forth in the appended claims. The invention itself, however, as well as a preferred mode of use, further objectives and advantages thereof, will best be understood by reference to the following detailed description of an illustrative embodiment when read in conjunction with the accompanying drawings, wherein:

Figure 1 is a diagram illustrating a distributed data processing system according to the present invention;

Figure 2 is an exemplary block diagram of a server according to the present invention;

Figure 3 is an exemplary block diagram of a client according to the present invention;

Figure 4 is an exemplary block diagram of the principle elements of a server in accordance with the present invention;

Figure 5 is an exemplary diagram illustrating an exemplary implementation of the present invention;

Figures 6A and 6B are flowcharts outlining an exemplary operation of the present invention; and

Figure 7 is an illustration of a display of a data stream from a client device implementing the present invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

With reference now to the figures, and in particular
5 with reference to **Figure 1**, a pictorial representation of
a distributed data processing system is depicted in which
the present invention may be implemented. Distributed
data processing system **100** is a network of computers in
which the present invention may be implemented.

10 Distributed data processing system **100** contains network
102, which is the medium used to provide communications
links between various devices and computers connected
within distributed data processing system **100**. Network
102 may include permanent connections, such as wire or
15 fiber optic cables, or temporary connections made through
telephone connections.

In the depicted example, server **104** is connected to
network **102**, along with storage unit **106**. In addition,
clients **108**, **110** and **112** are also connected to network
20 **102**. These clients, **108**, **110** and **112**, may be, for
example, personal computers or network computers. For
purposes of this application, a network computer is any
computer coupled to a network which receives a program or
other application from another computer coupled to the
25 network. In the depicted example, server **104** provides
data, such as boot files, operating system images and
applications, to clients **108-112**. Clients **108**, **110** and
112 are clients to server **104**. Distributed data
processing system **100** may include additional servers,
30 clients, and other devices not shown.

In the depicted example, distributed data processing

system **100** is the Internet, with network **102** representing a worldwide collection of networks and gateways that use the TCP/IP suite of protocols to communicate with one another. At the heart of the Internet is a backbone of high-speed data communication lines between major nodes or host computers consisting of thousands of commercial, government, education, and other computer systems that route data and messages. Of course, distributed data processing system **100** also may be implemented as a number of different types of networks such as, for example, an intranet or a local area network. **Figure 1** is intended as an example and not as an architectural limitation for the processes of the present invention.

Referring to **Figure 2**, a block diagram of a data processing system which may be implemented as a server, such as server **104** in **Figure 1**, is depicted in accordance with the present invention. Data processing system **200** may be a symmetric multiprocessor (SMP) system including a plurality of processors **202** and **204** connected to system bus **206**. Alternatively, a single processor system may be employed. Also connected to system bus **206** is memory controller/cache **208**, which provides an interface to local memory **209**. I/O bus bridge **210** is connected to system bus **206** and provides an interface to I/O bus **212**. Memory controller/cache **208** and I/O bus bridge **210** may be integrated as depicted. Peripheral component interconnect (PCI) bus bridge **214** connected to I/O bus **212** provides an interface to PCI local bus **216**. A number of modems **218-220** may be connected to PCI bus **216**. Typical PCI bus implementations will support four PCI expansion slots or add-in connectors. Communications

Docket No. AUS9-2000-0257-US1

links to network computers **108-112** in **Figure 1** may be provided through modem **218** and network adapter **220** connected to PCI local bus **216** through add-in boards. Additional PCI bus bridges **222** and **224** provide interfaces
5 for additional PCI buses **226** and **228**, from which additional modems or network adapters may be supported. In this manner, server **200** allows connections to multiple network computers. A memory mapped graphics adapter **230** and hard disk **232** may also be connected to I/O bus **212** as
10 depicted, either directly or indirectly.

Those of ordinary skill in the art will appreciate that the hardware depicted in **Figure 2** may vary. For example, other peripheral devices, such as optical disk drives and the like, also may be used in addition to or
15 in place of the hardware depicted. The depicted example is not meant to imply architectural limitations with respect to the present invention. The data processing system depicted in **Figure 2** may be, for example, an IBM RISC/System 6000, a product of International Business
20 Machines Corporation in Armonk, New York, running the Advanced Interactive Executive (AIX) operating system.

With reference now to **Figure 3**, a block diagram of a data processing system in which the present invention may be implemented is illustrated. Data processing system
25 **300** is an example of a client computer. Data processing system **300** employs a peripheral component interconnect (PCI) local bus architecture. Although the depicted example employs a PCI bus, other bus architectures, such as Micro Channel and ISA, may be used.

30 Processor **302** and main memory **304** are connected to PCI local bus **306** through PCI bridge **308**. PCI bridge **308**

Docket No. AUS9-2000-0257-US1

may also include an integrated memory controller and cache memory for processor **302**. Additional connections to PCI local bus **306** may be made through direct component interconnection or through add-in boards. In the
5 depicted example, local area network (LAN) adapter **310**, SCSI host bus adapter **312**, and expansion bus interface **314** are connected to PCI local bus **306** by direct component connection.

In contrast, audio adapter **316**, graphics adapter
10 **318**, and audio/video adapter (A/V) **319** are connected to PCI local bus **306** by add-in boards inserted into expansion slots. Expansion bus interface **314** provides a connection for a keyboard and mouse adapter **320**, modem **322**, and additional memory **324**.

15 In the depicted example, SCSI host bus adapter **312** provides a connection for hard disk drive **326**, tape drive **328**, CD-ROM drive **330**, and digital video disc read only memory drive (DVD-ROM) **332**. Typical PCI local bus implementations will support three or four PCI expansion
20 slots or add-in connectors.

An operating system runs on processor **302** and is used to coordinate and provide control of various components within data processing system **300** in **Figure 3**. The operating system may be a commercially available
25 operating system, such as OS/2, which is available from International Business Machines Corporation. "OS/2" is a trademark of International Business Machines Corporation.

An object oriented programming system, such as Java, may run in conjunction with the operating system,
30 providing calls to the operating system from Java programs or applications executing on data processing

2025 RELEASE UNDER E.O. 14176

Docket No. AUS9-2000-0257-US1

system **300**. Instructions for the operating system, the object-oriented operating system, and applications or programs are located on a storage device, such as hard disk drive **326**, and may be loaded into main memory **304** for execution by processor **302**.

Those of ordinary skill in the art will appreciate that the hardware in **Figure 3** may vary depending on the implementation. For example, other peripheral devices, such as optical disk drives and the like, may be used in addition to or in place of the hardware depicted in **Figure 3**. The depicted example is not meant to imply architectural limitations with respect to the present invention. For example, the processes of the present invention may be applied to multiprocessor data processing systems.

The present invention provides a mechanism by which a plurality of users, such as users of client devices **108**, **110** and **112**, may obtain full access to a system resource during a same session. Using the present invention, a user on a first client device may have full access to the same data stream as another user on a second client device during the same session. Furthermore, each user may add to the data stream as he/she sees fit and have their additions to the data stream shared with each of the users that are accessing the data stream during that session. Thus, with the present invention, each client device may have a private communication channel to the system resource which is not accessible by other client devices while the output from the resource is shared by all of the client devices participating in a session.

In order to provide the mechanism set forth above, a

Docket No. AUS9-2000-0257-US1

server, such as server **104**, implements a data stream splitter manager and one or more data stream splitters. **Figure 4** is an exemplary block diagram illustrating the primary elements of a server in accordance with the present invention. As shown in **Figure 4**, the server includes an input/output interface **410**, a data stream splitter manager **420**, a plurality of data stream splitters **430-450**, a data stream splitter table storage device **460**, and a buffer **470**. These elements are shown being coupled via a signal/data bus **480**, however any other mechanism for coupling these elements may be utilized without departing from the spirit and scope of the present invention. The elements **410-470** may be implemented as hardware, software, or a combination of hardware and software without departing from the spirit and scope of the present invention.

The data stream splitter manager **430** manages client device's access to the one or more data stream splitters. Each data stream splitter **430-450** handles a particular data stream to which the client devices may have access. The data stream splitters may be dynamically constructed/desconstructed as needed. For example, if a new session is initiated with a system resource that is not currently being handled by an existing data stream splitter, a new data stream splitter may be constructed to facilitate sharing of the data stream to and from the system resource. Similarly, once a session has ended, the data stream splitter for that session may be deconstructed if no longer needed.

While the preferred embodiments of the present invention will be described in terms of each data stream splitter **430-450** handling a single data stream, it is

Docket No. AUS9-2000-0257-US1

intended to be within the scope of the present invention that a single data stream splitter **430-450** may handle a plurality of different data streams. In such an embodiment, each data stream would be provided with an identifier that is recognizable by the data stream splitter **430-450** and utilized by the data stream splitter manager **420** to identify a data stream for a particular session.

With the present invention, a client device establishes a session for a data stream via the data stream splitter manager **420**. The client device establishes the session by sending a request message to the data stream splitter manager **420** via a network, such as network **102**, and input/output interface **410**. The request message includes client device characteristic information, e.g., network address, user identification, password, bit rate, and the like. The request message also includes an indicator of the system resource to which the client device desires access.

The data stream splitter manager **420** establishes a pseudo-terminal for the client device and stores client device information in a data stream splitter table in data stream splitter table storage device **460** for the particular data stream splitter handling the data stream. The data stream splitter table may be a single table having entries for all data stream splitters that are currently active or may be comprised of a plurality of tables, each designated for only a single data stream splitter.

The pseudo-terminal is used primarily for ease of use, setup control of communication characteristics, and reporting by tools which can key onto a pseudo-terminal

Docket No. AUS9-2000-0257-US1

name. The pseudo-terminal provides a mechanism by which the data stream splitter communicates with the client devices participating in a session through the data stream splitter manager **420**. While the preferred
5 embodiment of the present invention is described as making use of pseudo-terminals, the use of pseudo-terminals is not essential to the functioning of the present invention.

The client device information stored in the data
10 stream splitter table may include, for example, a client device identifier, network address, pseudo-terminal identifier, data stream splitter identifier, and the like. The data stream splitter table storage device **460** may be a shared storage device such that the data stream
15 splitters **430-450** may share access the storage device along with the data stream splitter manager **420**.

The data stream splitter cycles through the entries in its corresponding data stream splitter table in the data stream splitter table storage device **460**. As the
20 data stream splitter cycles through the entries, the data stream splitter provides a corresponding pseudo-terminal with access to the data stream and will begin sending the data stream output to the pseudo-terminal.

In the case where a large data stream splitter table
25 is used, only those pseudo-terminals associated with entries in the data stream splitter table identified as requesting access to the data stream handled by the data stream splitter will be provided access to the data stream. Other entries in the large data stream splitter
30 table will not be provided access to the data stream if they are not marked for attachment to that specific data stream. In the case where individual tables are being

Docket No. AUS9-2000-0257-US1

used for each data stream splitter, all of the pseudo-terminals associated with entries in the table will be provided access to the data stream in the manner set forth above.

5 In addition to sending the data stream to the client devices, the data stream splitter manager **420** receives input from the client devices and applies the input to the corresponding pseudo-terminal in accordance with the data stream splitter table in the data stream splitter
10 table storage device **460**. The results of a client device's input to the pseudo-terminal are then applied to the data stream and transmitted to each of the client devices participating in the session when the data stream splitter cycles through the entries in the data stream
15 splitter table. In this way, each client device has full access to modify the data stream with the results of the modification being sent to each of the other client devices participating in the session.

 In a preferred embodiment, the above process is
20 implemented on a character by character basis. For example, as a user of a client device types input to the data stream, each character typed is sent to the system resource for that data stream. In response, the system resource generates an output. The output from the system
25 resource is immediately sent, via the data stream, to each of the client devices requesting access to the data stream in a sequential and cyclical manner.

 Thus, if a first user is typing a command into his/her client device, each character is sent to the
30 system resource via the data stream. The system resource generates an output of a graphical character associated with the particular character input from the first user.

Docket No. AUS9-2000-0257-US1

This output is sent to each of the other client devices requesting access to the data stream. Thus, all of the client devices in the session will see the first user typing the command as if the first user were typing the
5 command directly using the particular client device. In this way, each user is provided with a realtime output from the system resource based on the input received from the other users and him/herself.

Client devices can join existing sessions via the
10 data stream splitter manager **420** by requesting access to the same system resource that is being access by another client device in an established session. When a client device joins an existing session, the client device information, pseudo-terminal information, and data stream
15 splitter information is added to the data stream splitter table maintained by the data stream splitter manager **420** in the data stream splitter table storage device **460**. Thereafter, the newly added client device is provided with full access to the data stream for that session.

20 In addition, the data stream splitter manager may include a buffer **470** of data from the data stream. This buffer **470** may store, for example, a predetermined amount of data obtained from the data stream for a past predetermined period of time. For example, the buffer
25 **470** may store data obtained from the data stream for the past minute of session time. When a new client device joins the session, the new client device may be provided with this buffered data to provide a context by which the new client device can being joining in the session. The
30 data in the buffer **470** may be continuously updated when the buffer **470** becomes full. Thereby, old data in the buffer **470** is cycled out, e.g., overwritten, when new

data is received.

Figure 5 is a block diagram illustrating an implementation of the present invention. As shown in **Figure 5**, a plurality of client devices **510-540** are involved in a number of sessions. Each client device **510-540** is capable of being a participant in a plurality of sessions. The sessions shown in **Figure 5** are implemented as "windows," which herein refers to a view port through which software is run under any operating system.

Each session is managed by one of the data stream splitter managers **550** and **560** and is handled by one of the data stream splitters **570-595**. Each data stream splitter **570-595** sends and receives data along one data stream, e.g., data stream 1, 2, 3 or 4.

In the specific example shown in **Figure 5**, there is one bi-directional input/output data stream per line between two entities. The data streams 1-4 are any data streams which would normally, in prior art systems, send output to and receive input from a single client device. These data streams may be, for example, data streams consisting of input/output to a debug application, a document editor, an application trace program, or any other type of system resource which may send output to a client device and/or receive input from a client device.

As shown in **Figure 5**, the client device **510** is involved in three sessions, all being managed by data stream splitter manager **550**. Each session is implemented as a pseudo-terminal in the data stream splitter manager, i.e. window A1, A2 and A3, and is handled by a different data stream splitter **570**, **580** and **590**, respectively. Client devices **530** and **540** are likewise involved in a

Docket No. AUS9-2000-0257-US1

plurality of sessions being managed by data stream splitter manager **550** and **560**. Client device **520** is involved in two sessions, window B1 and window B2, and is attempting to join a third session, window B3.

5 Thus, the data stream 1 is shared by client devices **510** and **520**. The data stream 2 is being accessed by only client device **510**. The data stream 3 is being shared by all four client devices **510-540**. Data stream 4 is being shared by client devices **530** and **540**, with client device
10 **520** attempting to share data stream 4.

 In the case of client device **520**, the client device attempts to join a session to share data stream 4 by connecting to a known port on server 2, on which data stream splitter manager **560** is operating. The data
15 stream splitter manager **560** forks a copy of itself, i.e. creates an additional instance of the currently running code, described more fully hereafter, to handle input/output to the client device **520** window B3. The data stream splitter manager **560** also opens a
20 pseudo-terminal for communication with data stream splitter **595**, which is already handling input/output between data stream 4 and windows C2 and D2 of client devices **430** and **440**.

 The forked copy of the data stream splitter manager
25 **560** then sets elements in the data stream splitter table to let the data stream splitter **595** know on what pseudo terminal the data stream splitter manager **560** will be communicating for the client device. When the data stream splitter **595** cycles through the entries in the
30 data stream splitter table, the data stream splitter **595** sends data stream 4 output to the various windows C2, D2

Docket No. AUS9-2000-0257-US1

and B3. The data stream splitter **595** also sends any input from the windows C2, D2 and B3 to the data stream 4. Should any of the client devices **510-540** disconnect from the data stream splitter manager **560**, the data stream splitter table will be updated accordingly by removing the entry for that pseudo-terminal and thus, the data stream splitter **595** will stop sharing the data stream 4 with that client device.

Furthermore, in an alternative embodiment, the data stream splitter manager **560** may maintain a data stream splitter table for a data stream splitter and a particular data stream even if all of the client devices involved in the session disconnect from the data stream splitter manager **560**. This maintaining of the data stream splitter table may be performed for a predetermined period of time, or may be maintained indefinitely until a command to logically remove the session from the data stream splitter table is received from a client device or network administrator, depending on the particular system requirements. In this way, all of the client devices may disconnect, such as at the end of a work day, and resume the session at a later time.

The data stream splitter manager of the present invention may be implemented as an application running on a server that is either apparent or unapparent to the client devices. For example, the data stream splitter manager may be implemented as an application used by a client device or may be implemented as a daemon process on a server that receives data from the client device and processes the data without the user of the client device being made aware of the presence of the data stream splitter manager.

Docket No. AUS9-2000-0257-US1

In a further implementation, the data stream splitter manager may be implemented as an application having a graphical user interface through which a user of a client device may select to start a new session, join
5 an existing session, leave a session, return to a session, or the like. In addition, various options such as displaying active connections, showing a listing of commands, obtaining on-line help and the like, may be provided.

10 In summary, in a particular embodiment of the present invention described above, the data stream splitter manager **560** listens for new connection requests from client devices, for example, on a known network port. When a connection is made from a client device,
15 the data stream splitter manager **560** forks a copy of the currently running code, i.e. the data stream splitter manager **560**, and returns to listening for the next new connection.

The forked copy of the data stream splitter manager
20 **560**, hereafter referred to as the client-specific server, may perform the following functions. The client-specific server exchanges/verifies software versions between the client device and the server and verifies any optional security information. This may include making sure the
25 connecting client device hostname is authorized, making sure the connecting client device username is authorized, prompting for and accepting/rejecting a password, making sure the system resource to be shared is authorized to be accessible by the client device, changing the username to
30 upgrade/downgrade authority, changing a group name to upgrade/downgrade authority, and the like.

The client-specific server may further handle

Docket No. AUS9-2000-0257-US1

command flag and menu requests to start a new data stream splitter, join an existing data stream splitter, look for a system resource already being multiplexed and then join a data stream splitter or start a new one as appropriate, 5 leave a current data stream splitter, report on current connections, quit a connection, and the like. Moreover, the client-specific server pipelines communication from data stream splitter code to client devices by reading data read from the pseudo terminals specific to this 10 unique combination of data stream splitter and client-specific server, then writing the same data over sockets network protocol to the client devices. Additionally, the client-specific server pipelines communication from client devices to data stream splitter 15 code by reading data form the client devices over the sockets network protocol and then writing the same data to the pseudo terminals specific to this unique combination of data stream splitter and client specific server.

20 The data stream splitter, such as data stream splitter **595**, uses non-blocking raw input so that any data from any connected client device will go directly to the data stream without any delay waiting for other client devices and without filtering any particular bit 25 patterns, such as escape sequences. By the term "non-blocking" what is meant is that there is no processing of the input by the client device prior to the input being sent to the data stream. Thus, as a user types a character on the client device, this character is 30 immediately sent to the data stream without waiting for the user to select a transmit function, press the "Enter" button, or the like. In this way, each client device

Docket No. AUS9-2000-0257-US1

participating in a session will be provided with realtime output from the system resource based on inputs received by the system resource from each of the client devices.

The data stream splitter accesses the particular
5 system resource by redirecting input and output to and from that system resource through a single point to single point communication path. The data stream splitter records streamed data coming out of the system resource into a playback buffer so the data stream
10 splitter can still be "seen" by clients who were not connected in time to see the output "live" at the time the system resource sent it. Additionally, the data stream splitter continually scans the data stream splitter table and connects those client devices
15 requesting to be connected, disconnects those client devices requesting to be disconnected, sends any data not yet sent to a client device from the multiplexed data stream to that client device using the pseudo-terminal for that client device, sends any data not yet sent to
20 the multiplexed data stream from the client device to the multiplexed data stream, and optionally exits when the number of connected client devices connected reaches zero.

Thus, with the present invention, the data stream
25 splitter manager spawns copies of itself as client-specific servers on an as needed basis. Similarly, the client-specific servers spawn data stream splitters on an as needed basis. The client device communicates with the data stream splitter manager just
30 long enough for the data stream splitter manager to create a client-specific server for that client device. Thereafter, the client device relays communication

Docket No. AUS9-2000-0257-US1

between the user and the client-specific server over the network.

As described above, the present invention provides a mechanism through which a plurality of client devices may share the same data stream and have full access to modify the shared data stream. In addition, the present invention provides a mechanism by which modifications made by one client device to a data stream are transmitted to all other client devices active during a session.

Figure 6A is a flowchart outlining an exemplary operation of a data stream splitter manager of the present invention when starting/joining a session to share a data stream. As shown in **Figure 6A**, the operation begins with a request for access to a data stream being received (step **610**). A pseudo-terminal is created for the client device (step **620**). An entry in the data stream splitter table for the requested data stream is added identifying the client device and the pseudo-terminal (step **630**). Thereafter, the data stream splitter manager sends any new data from the client device to the pseudo-terminal (step **640**) and any new data from the pseudo-terminal to the client device (step **650**).

The data stream splitter manager monitors for a disconnect from the client device (step **660**) and if the client device disconnects, removes the entry in the data stream splitter table for the client device (step **670**). Otherwise, if the client device does not disconnect, the data stream splitter manager returns to step **640**.

Figure 6B is a flowchart outlining an exemplary operation of a data stream splitter of the present invention when sending/receiving data to and from a data

Docket No. AUS9-2000-0257-US1

stream. As shown in **Figure 6B**, the operation starts with the data stream splitter reading an entry from the data stream splitter table in the data stream splitter manager (step **710**). The data stream splitter determines if the
5 current data stream splitter table entry is associated with the resource that this data stream splitter is serving (step **715**). If not, the operation jumps to step **740**; otherwise, the operation continues to step **720**.

The mutliplexer sends data from the data stream to
10 the pseudo-terminal associated with the entry from the data stream splitter table (step **720**). Thereafter, the data stream splitter sends any input from the pseudo-terminal to the data stream (step **730**). The data stream splitter then reads the next entry in the data
15 stream splitter table (step **740**) and returns to step **720**.

Figure 7 illustrates an example display from a client device of a shared session for a data stream. The particular application of the present invention shown in **Figure 7** is to a debug session for debugging a computer
20 program. However, one of ordinary skill in the art will appreciate that the present invention is not limited to any particular type of data stream. Rather, the present invention may be applied to any type of data stream including, audio, video, textual data streams and the
25 like.

As shown in **Figure 7**, the display includes a first listing of debug information with an identifier that the debugger has been entered via keyboard. Thereafter, a conversation commences between two users, using two
30 different client devices. The conversation is facilitated by the command prompt of the debugger application. Thus, because the textual comments of the

2025 RELEASE UNDER E.O. 14176

two users includes words not recognized by the debugger, some error statements are shown.

The comments from the two users are displayed as the user types them. In other words, the output seen by the users is raw output from the system resource. As a result, if a first user mistypes a command and backspaces to correct the command, the second user will see the typing of the mistyped command and the backspacing as it occurs. Similarly, if both users are typing commands at the same time, the result will be a garbled command interleaving both inputs from the users. Thus, the present invention provides a mechanism by which both users have complete and full access to the data stream at approximately the same time. Each user is provided with a realtime display of the modified data stream based on the inputs from the other user and him/herself.

It is important to note that while the present invention has been described in the context of a fully

Docket No. AUS9-2000-0257-US1

functioning data processing system, those of ordinary skill in the art will appreciate that the processes of the present invention are capable of being distributed in the form of a computer readable medium of instructions and a variety of forms and that the present invention applies equally regardless of the particular type of signal bearing media actually used to carry out the distribution. Examples of computer readable media include recordable-type media such a floppy disc, a hard disk drive, a RAM, CD-ROMs, and transmission-type media such as digital and analog communications links.

The description of the present invention has been presented for purposes of illustration and description, and is not intended to be exhaustive or limited to the invention in the form disclosed. Many modifications and variations will be apparent to those of ordinary skill in the art. The embodiment was chosen and described in order to best explain the principles of the invention, the practical application, and to enable others of ordinary skill in the art to understand the invention for various embodiments with various modifications as are suited to the particular use contemplated.

Docket No. AUS9-2000-0257-US1

CLAIMS:

What is claimed is:

1. A method of communicating between one and a
5 plurality of devices, comprising:
 receiving, from a device, input to an application
 data stream;
 receiving an output from the application data stream
 based on the received input and input from the plurality
10 of other devices; and
 providing the output to the device and the plurality
 of devices at substantially a same time, wherein only the
 output from the application data stream is shared by the
 device and the plurality of devices.
15
2. The method of claim 1, wherein output from the
 application data stream is shared by the device and the
 plurality of devices using a data stream splitter.
- 20 3. The method of claim 2, wherein the data stream
 splitter is dynamically constructed to provide shared
 access to the application data stream.
4. The method of claim 1, further comprising
25 establishing a pseudo-terminal for the device.
5. The method of claim 4, wherein output received by
 the data stream splitter from the application data stream
 is sent to the pseudo-terminal and data received by the
30 pseudo-terminal from the device is sent to the data
 stream splitter.

6. The method of claim 2, wherein receiving input to the application data stream includes:

cycling through entries in a data stream splitter
table to identify entries associated with the data stream
splitter; and

cyclically providing the device and other devices access to the application data stream based on the cycling through the entries in the data stream splitter table.

7. The method of claim 1, further comprising:
generating a data stream splitter to handle access
to the application data stream if the application data
stream is not already being handled by another data
stream splitter; and

adding an entry to a data stream splitter table for the device and the data stream splitter.

8. The method of claim 1, wherein the receiving input to an application data stream, receiving output from an application data stream, and the providing steps are performed by a data stream splitter manager.

9. The method of claim 8, wherein, when the data stream splitter manager receives a request for access to the application data stream from the device, the data stream splitter manager forks a copy of itself to handle the access to the application data stream for that device.

10. The method of claim 8, wherein the data stream splitter manager is transparent to a user of the device.

Docket No. AUS9-2000-0257-US1

11. The method of claim 8, wherein the data stream splitter manager includes a graphical user interface.

12. The method of claim 1, further comprising storing
5 data from the data stream in a buffer, wherein when the device is first provided access to the data stream, the contents of the buffer are streamed to the device.

13. A method of providing a device shared access to a
10 data stream, comprising:

receiving a request for access to the data stream from a device;

adding an entry to a data stream splitter table for the device; and

15 providing the device access to the data stream via a data stream splitter in accordance with the entry in the data stream splitter table, wherein providing the device access includes providing output from the data stream to the device and sending input from the device to the data
20 stream, and wherein the output from the data stream is provided in a realtime manner based on the input from the device and input received from at least one other device.

14. A method of providing a plurality of devices shared
25 access to a data stream, comprising:

receiving, from a device, input to the data stream; generating data stream output based on the input from the device; and

supplying the data stream output to other devices of
30 the plurality of devices in a sequential manner, wherein the input is non-blocking raw input that is received as the device generates the input on a character by

Docket No. AUS9-2000-0257-US1

character basis, and wherein the data stream output is generated on a character by character basis as the input is received.

- 5 15. A method of providing shared access to a bi-directional data stream, comprising:
- cycling through entries in a data stream splitter table, each entry in the data stream splitter table identifying a client device;
- 10 sending data from the data stream to the client device identified in each entry based on the cycling through of the entries; and
- receiving data from the client device identified in each entry, based on the cycling through of the entries,
- 15 and sending the data from the client device to the bi-directional data stream.
16. The method of claim 15, wherein access to the data stream is shared by a plurality of client devices based
- 20 on the entries in the data stream splitter table, each of the client devices having full access to the data stream.
17. The method of claim 15, wherein the client devices have a private communication channel to the data stream
- 25 but the output from the data stream is shared by all of the client devices.
18. The method of claim 15, wherein the sending and receiving steps are performed by a data stream splitter.
- 30 19. The method of claim 18, wherein the data stream splitter is dynamically constructed to provide shared

Docket No. AUS9-2000-0257-US1

access to the data stream.

20. The method of claim 15, wherein sending data from the data stream to the client device includes sending
5 data from the data stream splitter to a pseudo-terminal associated with the client device.

21. The method of claim 15, wherein receiving data from the client device includes receiving data from the client
10 device via a pseudo-terminal associated with the client device.

22. The method of claim 18, wherein the data stream splitter provides non-blocking raw input/output access to
15 the data stream.

23. A computer program product in a computer readable medium for providing a device shared access to a data stream, comprising:
20 first instructions for receiving a request for access to the data stream from a device;
second instructions for adding an entry to a data stream splitter table for the device; and
third instructions for providing the device access
25 to the data stream via a data stream splitter in accordance with the entry in the data stream splitter table.

24. The computer program product of claim 23, wherein
30 access to the data stream is shared with other devices, each of the device and the other devices having full access to the data stream.

Docket No. AUS9-2000-0257-US1

25. The computer program product of claim 23, wherein the device is provided a private communication channel to the data stream but the output from the data stream is shared by the device and other devices.

5

26. The computer program product of claim 23, further comprising fourth instructions for dynamically constructing the data stream splitter to provide shared access to the data stream.

10

27. The computer program product of claim 23, further comprising fourth instructions for establishing a pseudo-terminal for the device.

15

28. The computer program product of claim 27, wherein data received by the data stream splitter from the data stream is sent to the pseudo-terminal and data received by the pseudo-terminal from the device is sent to the data stream splitter.

20

29. The computer program product of claim 23, wherein the third instructions for providing the device access to the data stream include:

fourth instructions for cycling through the data stream splitter table to identify entries associated with the data stream splitter; and

fifth instructions for cyclically providing the device and other devices access to the data stream based on the cycling through the data stream splitter table.

30

30. The computer program product of claim 23, further comprising fourth instructions for determining if access

Docket No. AUS9-2000-0257-US1

to the data stream is being handled by a data stream splitter, wherein the second instructions for adding an entry to a data stream splitter table for the device include instructions for adding the entry to a data
5 stream splitter table associated with the data stream splitter.

31. The computer program product of claim 23, wherein the first, second and third instructions are implemented
10 by a data stream splitter manager.

32. The computer program product of claim 31, further comprising fourth instructions for forking a copy of the data stream splitter manager to handle the access to the
15 data stream for that device, when the data stream splitter manager receives the request from the device.

33. The computer program product of claim 23, further comprising:
20 fourth instructions for storing data from the data stream in a buffer; and
 fifth instructions for streaming the contents of the buffer to the device when the device is first provided access to the data stream.

25
34. An apparatus for providing a device shared access to a data stream, comprising:
 a data stream splitter; and
 a data stream splitter manager coupled to the data
30 stream splitter, wherein the data stream splitter manager receives a request for access to the data stream from a device, adds an entry to a data stream splitter table for

Docket No. AUS9-2000-0257-US1

the device, and provides the device access to the data stream via the data stream splitter in accordance with the entry in the data stream splitter table.

- 5 35. The apparatus of claim 34, wherein access to the data stream is shared with other devices, each of the device and the other devices having full access to the data stream.
- 10 36. The apparatus of claim 34, wherein the data stream splitter provides the device a private communication channel to the data stream but the output from the data stream is shared by the device and other devices.
- 15 37. The apparatus of claim 34, wherein the data stream splitter is dynamically constructed by the data stream splitter manager to provide shared access to the data stream.
- 20 38. The apparatus of claim 34, wherein the data stream splitter manager establishes a pseudo-terminal for the device.
- 25 39. The apparatus of claim 38, wherein data received by the data stream splitter from the data stream is sent to the pseudo-terminal and data received by the pseudo-terminal from the device is sent to the data stream splitter.
- 30 40. The apparatus of claim 34, wherein the data stream splitter manager provides the device access to the data stream by:

Docket No. AUS9-2000-0257-US1

cycling through the data stream splitter table to identify entries associated with the data stream splitter; and

5 cyclically providing the device and other devices access to the data stream based on the cycling through the data stream splitter table.

41. The apparatus of claim 34, wherein the data stream splitter manager determines if access to the data stream
10 is being handled by a data stream splitter, wherein adding an entry to a data stream splitter table for the device includes adding the entry to a data stream splitter table associated with the data stream splitter.

15 42. The apparatus of claim 34, wherein, when the data stream splitter manager receives the request from the device, the data stream splitter manager forks a copy of itself to handle the access to the data stream for that device.

20 43. The apparatus of claim 34, wherein the data stream splitter manager is transparent to a user of the device.

44. The apparatus of claim 34, wherein the data stream
25 splitter manager includes a graphical user interface.

45. The apparatus of claim 34, wherein the data stream splitter provides non-blocking raw input/output access to the data stream.

30 46. The apparatus of claim 34, further comprising a buffer, wherein data from the data stream is stored in

Docket No. AUS9-2000-0257-US1

the buffer, and wherein when the device is first provided access to the data stream, the contents of the buffer are streamed to the device.

5 47. A method of communicating between one and a plurality of devices, comprising:

receiving from at least two of the plurality of devices, input to an application;

10 combining the input from the at least two of the plurality of devices to produce combined output; and simultaneously outputting the combined output at each of the plurality of devices.

15 48. A method of communicating between one and a plurality of devices, comprising:

receiving, from a device, input to an application;

receiving an output from the application based on the received input and input from one or more of the plurality of other devices; and

20 providing the output to each of the plurality of devices at substantially a same time.

49. A method of displaying an output display from an application shared by a plurality of devices, comprising:

25 receiving input from at least two of the plurality of devices;

combining the input from the at least two of the plurality of devices; and

30 displaying, substantially simultaneously, an output display based on the combined input from the at least two of the plurality of devices at the at least two of the plurality of devices.

2025 RELEASE UNDER E.O. 14176

ABSTRACT OF THE DISCLOSURE**APPARATUS AND METHOD FOR PROVIDING ACCESS TO A DATA****5 STREAM BY A PLURALITY OF USERS AT A SAME TIME**

10 An apparatus and method for providing access to a
data stream by a plurality of users at a same time. The
apparatus and method include a data stream splitter
manager which listens for new connections from client
15 devices. When a new connection from a client device is
identified, the data stream splitter manager generates a
pseudo-terminal for the client device and adds the client
device and pseudo-terminal information to a data stream
splitter table. In addition, if a data stream splitter
20 is not already established for handling data transfer
between the data stream splitter manager and a requested
resource, a new data stream splitter may be generated to
handle the data transfer. Thereafter, the data stream
splitter searches the data stream splitter table for
25 client devices participating in a session for sharing the
system resource. Data from a data stream associated with
the shared system resource is sent by the data stream
splitter to the pseudo-terminals associated with the
30 client devices. Data from the client devices is sent to
the pseudo-terminals and then to the data stream via the
data stream splitter. In this way, each client device
involved in the session has full access to the shared
system resource and output from the shared system
resource is provided to each of the client devices
involved in the session.

The diagram illustrates a system architecture for a data stream splitter. It features a central horizontal bus, labeled 480, which connects various components. Above the bus, from left to right, are the Input/Output Interface (410), the Data Stream Splitter Manager (420), the Data Stream Splitter Table Storage Device (460), and a Buffer (470). Below the bus, from left to right, are three Data Stream Splitter units, labeled 430, 440, and 450. Each component is connected to the central bus 480 via a bidirectional arrow, indicating two-way communication.

DECLARATION AND POWER OF ATTORNEY FOR
PATENT APPLICATION

As a below named inventor, I hereby declare that:

My residence, post office address and citizenship are as stated below next to my name;

I believe I am the original, first and sole inventor (if only one name is listed below) or an original, first and joint inventor (if plural names are listed below) of the subject matter which is claimed and for which a patent is sought on the invention entitled

APPARATUS AND METHOD FOR PROVIDING ACCESS TO A DATA
STREAM BY A PLURALITY OF USERS AT A SAME TIME

the specification of which (check one)

X is attached hereto.

— was filed on _____
as Application Serial No. _____
and was amended on _____
(if applicable)

I hereby state that I have reviewed and understand the contents of the above identified specification, including the claims, as amended by any amendment referred to above.

I acknowledge the duty to disclose information which is material to the patentability of this application in accordance with Title 37, Code of Federal Regulations, §1.56.

I hereby claim foreign priority benefits under Title 35, United States Code, §119 of any foreign application(s) for patent or inventor's certificate listed below and have also identified below any foreign application for patent or inventor's certificate having a filing date before that of the application on which priority is claimed:

Prior Foreign Application(s):	Priority Claimed
_____ (Number)	____ Yes ____ No
_____ (Country)	
_____ (Day/Month/Year)	

I hereby claim the benefit under Title 35, United States Code, §120 of any United States application(s) listed below and, insofar as the subject matter of each of the claims of this application is not disclosed in the prior United States application in the manner provided by the first paragraph of Title 35, United States Code, §112, I acknowledge the duty to disclose information material to the patentability of this application as defined in Title 37, Code of Federal Regulations, §1.56 which occurred between the filing date of the prior application and the national or PCT international filing date of this application:

(Application Serial #)	(Filing Date)	(Status)
------------------------	---------------	----------

I hereby declare that all statements made herein of my own knowledge are true and that all statements made on information and belief are believed to be true; and further that these statements were made with the knowledge that willful false statements and the like so made are punishable by fine or imprisonment, or both, under Section 1001 of Title 18 of the United States Code and that such willful false statements may jeopardize the validity of the application or any patent issued thereon.

POWER OF ATTORNEY: As a named inventor, I hereby appoint the following attorneys and/or agents to prosecute this application and transact all business in the Patent and Trademark Office connected therewith.

John W. Henderson, Jr., Reg. No. 26,907; Thomas E. Tyson, Reg. No. 28,543; James H. Barksdale, Jr., Reg. No. 24,091; Casimer K. Salys, Reg. No. 28,900; Robert M. Carwell, Reg. No. 28,499; Douglas H.
